SPEAR — 1972. This photo of the first storage ring at SLAC was proudly completed with typed-on performance figures. The view is from the east end of the site looking over the Research Yard.

Control Room (1972) Positron Source (1964)

The positron beam at SLAC will be produced by the method developed by Pine and Yount at the Stanford Mark III linear accelerator.¹ Electrons are accelerated to some relatively high energy and then hit a thick radiator inserted in the machine. The radiator thickness (several radiation lengths, typically) is chosen to be that at which the maximum number of charged particles exists in the shower induced by the incident electron. That part of the accelerator downstream of the radiator is adjusted to accelerate positrons. At shower maximum in the radiator most of the positrons have energies near the critical energy in the material. Mark III experiments have shown that in tantalum most of the positron energies lie between zero and 20 MeV. This whole energy bin is accelerated to a high energy; the positrons have the same absolute energy spread at any final energy.

The present conversion efficiency f measured at Mark III for 500 MeV electrons incident on a 3.2 radiation length target is²

$$f = 2 \times 10^{-4} e^+/e^-$$

for a positron energy spread of 20 MeV, within the phase-space acceptance of the accelerator. This measurement was made by comparing the current of positrons accelerated to 500 MeV, within a 20 MeV spread, with the electron current incident on the radiator.

The conversion efficiency is approximately proportional to the energy of the electron incident on the radiator, and hence we can simply scale the efficiency measured at Mark III in order to compute the positron beam intensity expected at SLAC. The number of positrons per pulse within the storage ring acceptance is given by

$$N_+ = f \times \frac{E}{500} \times \frac{\Delta E}{20} \times N_-$$

Thesis Acknowledgments

ACKNOWLEDGMENTS

It is a pleasure to acknowledge the contributions of the many members of the SLAC-LBL Magnetic Detector Group and also to thank the SPEAR staff and operators for the successful construction and operation of the storage ring which made this experiment possible. I would also like to thank my advisor, W. Chinowsky, for making my graduate experience a pleasant one and for his many discussions and suggestions during the course of this work. I am pleased also to acknowledge the contribution of B. Richter who kept track of my work at SLAC and several times initiated the discussions which got the analysis moving again after difficulties had slowed it down. I must also thank M. Breidenbach, A. Boyarski, C. Morehouse, R. Schwitters, and H. Lynch for countless discussions both of the physics results and the day-to-day problems of the analysis. Finally, to Jeanne Miller, who had to type this, my apologies.

Stories

Wiring with Scott

Scott and I, travelling daily from Berkeley in an LBL car, were given the job (by Marty) of connecting said, the TDCs . Seemed simple enough, so we got to work. The cables were 4ns Lemo and went from the discriminators to the TDC via 4ns LEMO cables. There were a lot of cables sand a crate full of camac module so we carefully checked everything and went back to Berkeley in the evening rush. There were a lot of cables completely covering the crate, so we were quite proud of our work.

and Marty

When we returned the next morning , we were surprised at what we saw. The cables had been completely redone by Marty. They were neatly bundles and bound with cable ties. The face of the modules were no longer covered. Instead, it was easy to extract a module and be reasonably sure that only the few cables removed were to be plugged back in. (required a special tool).

High Voltage with Rudy

I was on the night shift with Rudy Larson. One experienced physicist and one grad student. When the beam crashed and the klystron needed to be reset, we headed out the side door of the control room to the klystron cabinet. We needed a tall ladder and a hook to ground the top of the unit. Just before heading up, Rudy turned to me and said, “do you know CPR ”. I said no and held the ladder tight. (Later at CERN I learned CPR, fire fighting, and putting out electrical fires.)

More stories

Choice of running energies

I don't know who I asked, but when it was decided to start at 3.0,3.8,4.8 for high statistics and scan in 100 MeV intervals, I asked why it was as large as 100 MeV. The answer had something to do with the scale of strong interactions at high energies.

Strike and energy setting

In the middle of the runs, there was a strike by the operators, so the machine was run instead by physicists. The energy was set by a n oscillator in the control room .

You needed to be sure that you did not cross any resonances of which there were many.

Tracking names -> Pearl

The original names of the tracking routines were Marsha, Elsie, Doreen, and Pearl, but eventually it was just Pearl – another story.

Vertex finding and fitting Circe and dumpdup and Boojum and Snark

I was also writing code to find vertices and to combine that with better recalculations of the track momenta.. This led to circe, dumpdup, boojum, and Snark. Those of you familiar with Alice might see something here and the code was full of quotes from CS Lewis.

Burt and tracking/leaving/returning

I went to SLAC almost daily during the runs, and while there often met with Burt – he was really interested in the tracking and often had very good suggestions.

Problems in events with Converter

Note above picture taken with $MODE(9)=0$ so we see tracks before dump-dep selection. After selection, only one track is left but this should have been corrected (ie. the two tracks duplicate on chamber #1 but have opposite charge so this should be allowed)

Point out indicates that tracks duplicate on chamber #1 only. The point is a 4-wire point. There are two points on chamber #1

but only 1 gets used

| | | | | | | |
|--------|--------|-------|--------|----------------------------------|--------|--------|
| 4 wire | Φ | 2.185 | 2.183 | 1 tracks both come from level 4) | Φ | 2.186 |
| | Z | -315 | -291 | | Z | -220 |
| | R | .6435 | .66682 | | R | .66672 |

Obviously the fix put in for allowing duplication on chamber 1 is not working. Looked at code and found

```
DO 150 J=1,NTK
  ITR = IDUP(I,J)
  IF (TRKSUD(ITR).LT.0) GO TO 150
  IF (CHMB1.AND. SIZN(1.,COMMON(ISUB+1)).NE. CHARGE) GO TO 150
  ISUB = TRKPTR(ITR)
```

Note ISUB is in wrong place. Will fix and rescue trouble events. Above plus error in setting of logical variable chmb1 has fixed this event. Have verified operation of converter vertex calculation on this one.

One of many examples where Z values of tracks near conversions do not seem to be optimal. Further, what would seem to be the best track has not been found by the tracking routines.

Track 6 as shown is

Fit to tracks (thesis)

Pg 33

a) Circle Fit

The equations for a least-square fit to a circle are

$$\chi^2 = \sum_i (r_i - \rho)^2 \quad r_i = [(x_i - x_0)^2 + (y_i - y_0)^2]^{1/2}$$

$$\frac{\partial \chi^2}{\partial \rho} = 0, \quad \frac{\partial \chi^2}{\partial x_0} = 0, \quad \frac{\partial \chi^2}{\partial y_0} = 0$$

$$\rho = \frac{\sum r_i}{N}, \quad x_0 = \frac{\sum x_i}{N} - \frac{\rho}{N} \sum \frac{x_i - x_0}{r_i}, \quad y_0 = \frac{\sum y_i}{N} - \frac{\rho}{N} \sum \frac{y_i - y_0}{r_i}$$

The equations are highly coupled, and there is no convenient

way to iterate them. The problem of fitting points to a circle has been solved by Ascoli. The method consists of

minimizing

$$\begin{aligned} \chi_A^2 &= \sum_i \left[\frac{r_i^2 - \rho^2}{2\rho} \right]^2 \\ &= \sum_i (r_i - \rho)^2 \left(\frac{r_i + \rho}{2\rho} \right)^2 \\ &= \sum_i (r_i - \rho)^2 \left[1 + \frac{r_i - \rho}{2\rho} \right]^2 \\ &= \sum_i (r_i - \rho)^2 \left[1 + \frac{(r_i - \rho)^2}{4\rho^2} \right] \end{aligned}$$

$$\sin \frac{\phi}{2} = \frac{R/2}{\rho} \quad \text{where } R \text{ is the radius of point } P$$

so that

$$\phi = 2 \sin^{-1} \frac{R}{2\rho} + \phi_0$$

$$\phi = \phi_0 + 2 \left\{ \frac{R}{2\rho} + \frac{1}{3!} \left(\frac{R}{2\rho} \right)^3 + \frac{3}{5!} \left(\frac{R}{2\rho} \right)^5 + \dots \right\}$$

In cases where $\frac{1}{3!} \left(\frac{R}{2\rho} \right)^2 \ll 1$, the radius of curvature and initial angle of the track can be estimated by using

$$\phi_1 = \phi_j + \frac{R_1}{\rho}$$

$$\phi_2 = \phi_0 + \frac{R_2}{\rho}$$

$$\left(\phi_1 - \frac{R_1}{\rho} \right) = \left(\phi_2 - \frac{R_2}{\rho} \right)$$

$$\rho = \frac{R_1 - R_2}{\phi_1 - \phi_2}, \quad \phi_0 = \phi_1 - \frac{R_1}{\rho}$$

R_1 and R_2 are approximately 1.4 and 1.1 respectively so that

Thesis pg 36 z fi

-36-

to a helix. Thus, the fit for Z_0 (the origin in Z) and $\tan\lambda$ (the tangent of the dip angle) uses

$$Z_i = Z_0 + S_i \tan\lambda$$

where

$$S_i = 2\rho \sin^{-1} \left(\frac{L_i}{2\rho} \right)$$

$$L_i = [(X_i - X_0)^2 + (Y_i - Y_0)^2]^{1/2}$$

with X_0, Y_0, ρ determined by the XY fit. The method is to minimize

$$\chi_Z^2 = \sum \frac{[Z_i - (Z_0 + S_i \tan\lambda)]^2}{\sigma_i^2}$$

where σ_i is used to account for the different resolution on the 4° and 2° spark gaps. The solutions of the minimization equations are

$$\tan\lambda = \frac{\left(\sum \frac{Z_i S_i}{\sigma_i^2} \right) \left(\sum \frac{1}{\sigma_i^2} \right) - \left(\sum \frac{Z_i}{\sigma_i^2} \right)}{D}$$

$$Z_0 = \frac{\left(\sum \frac{S_i^2}{\sigma_i^2} \right) \left(\sum \frac{Z_i}{\sigma_i^2} \right) - \left(\sum \frac{S_i}{\sigma_i^2} \right) \left(\sum \frac{Z_i S_i}{\sigma_i^2} \right)}{D}$$

where

$$D = \left(\sum \frac{S_i^2}{\sigma_i^2} \right) \left(\sum \frac{1}{\sigma_i^2} \right) - \left(\sum \frac{S_i}{\sigma_i^2} \right)^2$$

 Best point on all of remaining chambers.

calculation of the Error in point at closest approach as a function of momentum.

see statement
 the track is known with an error comparable to the spark chamber resolution at its midpoint. Thus, for a track which ends the 4 spark chambers, one knows the track position intercept to the track level at a radius of 1 meter. it then are the propagated errors in the point of closest approach?

We need to calculate (d-p')

$$d^2 = L^2 + p'^2 - 2p'L \cos(\theta)$$

$$p^2 = L^2 + p'^2 - 2pL \cos \theta \Rightarrow \cos \theta = \frac{L}{2p}$$

$$d^2 = L^2 + p'^2 - \frac{2p'}{2p} L^2$$

$$= L^2 + (p - \Delta p)^2 - L^2 \frac{(p - \Delta p)}{p}$$

$$d \cdot p' = \sqrt{L^2 + (p - \Delta p)^2 - L^2 \frac{(p - \Delta p)}{p}} - (p - \Delta p)$$

ABSTRACT

We have observed a very sharp peak in the cross section for $e^+e^- \rightarrow$ hadrons, e^+e^- , and possibly $\mu^+\mu^-$ at a center-of-mass energy of 3.105 ± 0.003 GeV. The upper limit to the full width at half maximum is 1.3 MeV.

ABSTRACT

We have observed a second sharp peak in the cross section for $e^+e^- \rightarrow$ hadrons at a center-of-mass energy of 3.695 ± 0.004 GeV. The upper limit of the full width at half maximum is 2.7 MeV.

Summary of Key Numbers, Assumptions & Results
(after a check with Roy Schwitters at 11:15 am)

$$\Delta W = 1.3 \text{ MeV}$$

$$W = 3.105 \pm 0.003 \text{ GeV}$$

$$\Gamma_{\text{obs}} = 1.25 \pm 0.2 \text{ MeV}$$

\therefore consistent with very small Γ .

Upper limit: $\Gamma \leq 0.67 \text{ MeV}$.

$$(\sigma_{\mu\mu})_{\text{QED}} = 9.03 \text{ nrb}$$

Bars on top of quantities means folded with resolution function, i.e. observed quantities.

$$(\overline{\sigma}_{\text{total}})_{\text{max}} = (2300 \pm 200) \times 1.39 = 3200 \pm 280 \text{ nrb}$$

Correction for radiative tail

$$(\Delta\overline{\sigma}_{\mu\mu})_{\text{max}} = 80 \pm 20 \text{ nrb}$$

[This is 2-body, coplanar, not electrons, events - assumed to be $\mu\mu$ in what follows.]

$$(\overline{\sigma}_{\mu\mu})_{\text{max}} = (80 \pm 20) \times 1.39 \times \frac{1}{0.55} = 200 \pm 50 \text{ nrb}$$

$$\overline{r}_{\text{max}} = (\overline{\sigma}_{\mu\mu})_{\text{max}} / (\sigma_{\mu\mu})_{\text{QED}} = 22 \pm 5.5$$

Assumptions

- (1) $J=1$ resonance
- (2) No other interference at peak
- (3) Resolution function is Breit-Wigner with $\text{FWHM} = \Delta W$.

$$\text{Then } (\overline{\sigma}_{\text{obs}})_{\text{max}} = \frac{12\pi}{W^2} \frac{\Gamma_e \Gamma_e}{\Gamma(\Gamma + \Delta W)}; \quad (\overline{\sigma}_{\text{total}})_{\text{max}} = \frac{12\pi}{W^2} \frac{\Gamma_e}{\Gamma(\Gamma + \Delta W)}$$

$$\text{With } W = 3.105 \text{ GeV}, \quad \frac{12\pi}{W^2} = 1.521 \times 10^6 \text{ nrb}$$

$$\text{From } (\overline{\sigma}_{\text{total}})_{\text{max}} = 3200 \pm 280 \text{ nrb}, \quad \frac{\Gamma_e}{\Gamma + \Delta W} = (2.1 \pm 0.2) \times 10^{-3}$$

$$\text{If } \Gamma \ll \Delta W \text{ (see below), } \Gamma_e = (2.7 \pm 0.3) \text{ keV}$$

(*) Assume $\Gamma_e = \Gamma_\mu$.

$$\text{Then from } (\overline{\sigma}_{\mu\mu})_{\text{max}} = 200 \pm 50 \text{ nrb}, \quad \frac{\Gamma + \Delta W}{\Gamma} = 28 \pm 8$$

$$\text{Thus } \Gamma \ll \Delta W \text{ is confirmed and } \Gamma = \frac{1.3 \times 10^3}{28 \pm 8} = 46 \pm 19 \text{ keV}$$

$$\frac{\Gamma_e}{\Gamma} \approx 0.06 \quad (\text{in agreement with } \frac{(\overline{\sigma}_{\mu\mu})_{\text{max}}}{(\overline{\sigma}_{\text{total}})_{\text{max}}} = \frac{200}{3200} = 0.063)$$

Notes on the decay $\Psi(3695) \rightarrow \Psi(3105) \pi^+ \pi^-$ 30-11-74 1

The decay of $\Psi' \rightarrow \Psi \pi^+ \pi^-$ is apparently a significant fraction of the hadronic decays of the $\Psi(3695)$, called Ψ' here. There is a signal in the 4-prong $(e^+ e^-) \pi^+ \pi^-$, as well as the strong peak at $M \approx 3.1$ GeV in the mass spectrum receiving against the $\pi^+ \pi^-$ (but not $\pi^+ \pi^+$) pair.

I. Assumptions

1. If this decay mode is an appreciable fraction of the Ψ' decays, it argues strongly for the Ψ and Ψ' having some new quantum number in common, a quantum number that inhibits decay directly into ordinary hadrons. We thus assume that Ψ' and Ψ are $C=-1$, $J=1$, $I=0$ objects with color or charmishness. [If Han-Nambu scheme, then color octet and ordinary SU(3) singlets. If charm, then $(\bar{c}c)$ states, analogous to the $\Phi(1020)$ as a $(\bar{\lambda}\lambda)$ state.]

2. With $I=0$ for both, single pion emission is forbidden by isospin. Then 2-pion decay with $I=0$ (1-wave) is most likely.

3. The effective interaction is assumed to be

$$H_{int} = g (\Psi_\mu \Psi'^\mu) \phi_{\pi^+} \phi_{\pi^-}$$

where Ψ_μ, Ψ'_μ are the vector fields describing the Ψ and Ψ' particles and g is a dimensionless coupling constant.

II. Kinematics

Define the masses as follows (all in MeV):

$$M = 3695, \quad m = 3105, \quad \mu = 140$$

The mass difference is $\Delta M = 590$ MeV.
